Last time

- I motivated the study of certain limitations of probabilistic computation using tools from algorithmic randomness and computability theory.
- I introduced the basics of algorithmic randomness and discussed my preferred model of probabilistic computation.
- ► I introduced the notion of a negligible Π⁰₁ class and discussed some basic results about such classes.

Today, I will

- 1. introduce the notion of a deep Π_1^0 class;
- 2. prove a number of basic results about deep classes;
- outline the proof that the collection of consistent completions of Peano arithmetic is a deep class, and
- 4. provide several other examples of deep classes.

Outline of today's talk

- 1. Review
- 2. Introducing deep Π_1^0 classes

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

3. Examples of Π_1^0 classes

1. Review

<□ > < @ > < E > < E > E のQ @

Recall...

- ► Martin-Löf random sequences: Infinite binary sequences that avoid a family of effective null subsets of 2^ω.
- Probabilistic computation: Turing computation with an algorithmically random oracle (usually a Martin-Löf random sequence).
- Π_1^0 classes: Effectively closed classes, or equivalently:
 - the collection of infinite paths through a computable tree; or

the collection of infinite paths through a co-c.e. tree.

Further recall...

- S ⊆ 2^ω is negligible if there is no probabilistic procedure for computing a member of S with positive probability.
- A left-c.e. semi-measure can be seen as a super-additive measure that can be computably approximated from below.
 - There is a correspondence between left-c.e. semi-measures and Turing functionals.

- ► There is a universal left-c.e. semi-measure *M*.
- ▶ $S \subseteq 2^{\omega}$ is negligible if and only if $\overline{M}(S) = 0$, where \overline{M} is the largest measure such that $\overline{M} \leq M$.

2. Introducing Deep Π_1^0 classes

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

Unlike negligibility, we only define depth for Π_1^0 classes.

Depth is a property that is strictly stronger than negligibility for Π_1^0 classes.

Instead of considering how difficult it is to produce a path through a Π_1^0 class \mathcal{P} , we can consider how difficult it is to produce an *initial segment* of some path through \mathcal{P} , level by level.

Deep Π_1^0 classes are the "most difficult" Π_1^0 classes in this respect.

Some notation

Let $\mathcal{P} \subseteq 2^{\omega}$ be a Π_1^0 class.

Let $T_{\mathcal{P}} \subseteq 2^{<\omega}$ be the set of extendible nodes of \mathcal{P} ,

$$T_{\mathcal{P}} = \{ \sigma \in 2^{<\omega} : \llbracket \sigma \rrbracket \cap \mathcal{P} \neq \emptyset \}.$$

Thus $T_{\mathcal{P}}$ is the canonical co-c.e. tree such that $\mathcal{P} = [T_{\mathcal{P}}]$ (the set of infinite paths through $T_{\mathcal{P}}$).

Hereafter T will stand for $T_{\mathcal{P}}$.

For each $n \in \omega$, T_n consists of all strings in T of length n.

Deep classes: the definition

Let \mathcal{P} be a Π_1^0 class and let T be the canonical co-c.e. tree such that $\mathcal{P} = [T]$.

 $\mathcal P$ is a *deep class* if there is some computable, non-decreasing, unbounded function $h:\omega\to\omega$ such that

 $M(T_n) \leq 2^{-h(n)},$

where $M(T_n) = \sum_{\sigma \in T_n} M(\sigma)$.

That is, the probability of producing some initial segment of a path through \mathcal{P} is effectively bounded from above.

Note: Every deep class is negligible.

(日) (四) (코) (코) (코) (코)

Why use the co-c.e. tree in the definition of depth?

For every Π_1^0 class \mathcal{P} there is a computable tree $S \subseteq 2^{<\omega}$ such that $\mathcal{P} = [S]$.

Why can't we use this computable tree S in the definition of depth?

First, in general, S will contain non-extendible nodes, so even if we can compute some element in S_n , we still may fail to compute an initial segment of a member of \mathcal{P} .

But this observation doesn't rule out the possibility that we can define depth in terms of computable trees.

Theorem (Bienvenu, Porter)

Let S be a computable tree. Then there is no computable order h such that $M(S_n) \leq 2^{-h(n)}$ for every $n \in \omega$.

Corollary (Bienvenu, Porter)

Let S be a tree with a computable sub-tree. Then there is no computable order h such that $M(S_n) \leq 2^{-h(n)}$ for every $n \in \omega$.

Case 1: S has only finitely many non-extendible nodes.

Case 1: S has only finitely many non-extendible nodes.

In this case, the left-most path of S is computable.

Case 2: S has infinitely many non-extendible nodes.

Case 2: S has infinitely many non-extendible nodes.

In this case, first we find a sequence of non-extendible nodes of increasing length.

Case 2: S has infinitely many non-extendible nodes.

In this case, first we find a sequence of non-extendible nodes of increasing length.

Case 2: S has infinitely many non-extendible nodes.

In this case, first we find a sequence of non-extendible nodes of increasing length.

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

In this case, first we find a sequence of non-extendible nodes of increasing length.

$$\sum_{n \in \mathbb{N}} 2^{-f(n)} \le 1.$$

Computing members of deep Π_1^0 classes

What level of randomness \mathcal{R} guarantees that no \mathcal{R} -random sequence can compute a member of a deep Π_1^0 class?

The answer is known as *difference randomness*, which is formulated in terms of *difference tests*: a collection of pairs of uniformly effectively open subsets $(\mathcal{U}_i, \mathcal{V}_i)_{i \in \omega}$ of 2^{ω} such that $\lambda(\mathcal{U}_i \setminus \mathcal{V}_i) \leq 2^{-i}$.

Theorem (Bienvenu, Porter)

If $X \in 2^{\omega}$ is difference random, then X cannot compute any member of a deep Π_1^0 class.

Note: The difference random sequences are precisely the Martin-Löf random sequences that cannot compute a completion of PA.

3. Examples of deep Π_1^0 classes

<□ > < @ > < E > < E > E のQ @

Paradigm example: Consistent completions of PA

The following is implicit in work of Levin and Stephan.

Theorem The Π_1^0 class of consistent completions of PA is a deep class.

What exactly does this tell us?

Not only can we not probabilistically compute some consistent completion of *PA* with positive probability, but we cannot even hope to produce longer and longer initial segments of a consistent completion of *PA* with sufficiently high probability.

Completions of PA proof sketch, 1

To prove that this result, we can consider the class \mathcal{P} of total extensions of a universal partial computable $\{0, 1\}$ -valued function.

Let $u(\langle e, x \rangle) = \phi_e(x)$, where $(\phi_e)_{e \in \omega}$ is an effective enumeration of all partial computable $\{0, 1\}$ -valued functions.

We will define a partial computable $\{0, 1\}$ -valued function ϕ_e (where we know *e* in advance by the recursion theorem), and this will allow us to show that \mathcal{P} is deep.

Completions of PA proof sketch, 2

Since we are defining ϕ_e , we have control of the values $u(\langle e, x \rangle)$ for every $x \in \omega$.

Let $(I_k)_{k\in\omega}$ be an effective collection of intervals forming a partition of ω , where we have control of 2^{k+1} values of u inside of I_k for each $k \in \omega$.

Completions of PA proof sketch, 3

Step 1: For each k, we consider the sets

$$E_{k,s} = \{ \sigma \in 2^{<\omega} : \sigma \upharpoonright I_k \text{ extends } u_s \upharpoonright I_k \},\$$

and wait for a stage s such that

$$M(E_{k,s})\geq 2^{-k}.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Completions of PA proof sketch, 4

Step 2: Pick some $y \in I_k$ on which we have yet to define u.

Consider the sets

$$E^0_{k,s}(y) = \{\sigma \in E_{k,s} : \sigma(y) = 0\}$$

and

$$E^1_{k,s}(y) = \{ \sigma \in E_{k,s} : \sigma(y) = 1 \}.$$

Then $M(E_{k,s}^{i}(y)) \ge 2^{-(k+1)}$ for i = 0 or 1 (or both).

If this holds for i = 0, we set u(y) = 1; otherwise we set u(y) = 0.

(ロ)、(型)、(E)、(E)、(E)、(O)へ(C)

Completions of PA proof sketch, 5

We repeat the process, going back to Step 1.

We can repeat the process at most 2^{k+1} times (since we have enough values to work with in I_k).

Eventually, we will get stuck at Step 1.

Setting $f(k) = \max(I_k)$, we will have

 $M(\{\sigma:\sigma| f(k) \text{ extends } u\}) \leq 2^{-k}.$

That is,

$$M(T_{f(k)}) \leq 2^{-k}.$$

Establishing the depth of a given Π_1^0 class

The technique for showing that the class of consistent completions of PA is deep is what we refer to as a *wait and kill* argument.

We need to work with some object that we have control over in some way.

For example, in the previous proof we define a partial computable $\{0,1\}$ -valued function ϕ using the recursion theorem.

We wait to see a sufficiently large collection of oracles compute some possible extension of ϕ (at some place at which ϕ is currently undefined).

We then define ϕ at this place in such a way as to $\it kill$ off each of these oracles.

Shift-complex sequences: the idea

A Martin-Löf random sequence X has high initial segment complexity, satisfying

$$K(X \upharpoonright n) \ge n - O(1).$$

Nonetheless, X will still contain arbitrarily long runs of 0s (since all Martin-Löf random sequences are normal).

That is, certain subwords of X can have fairly low initial segment complexity.

By contrast, a shift-complex sequence is a sequence with the property that every subword has high initial segment complexity.

Shift-complex sequences: the formal definition

For $\delta \in (0,1)$ and $c \in \omega$, we say that $X \in 2^{\omega}$ is (δ, c) -shift complex if

$$\mathsf{K}(\tau) \geq \delta |\tau| - c$$

for every subword τ of X.

The following draws upon work of Rumyantsev.

Theorem (Bienvenu, Porter) For every $\delta \in (0, 1)$ and $c \in \omega$, the (δ, c) -shift complex sequences form a deep class.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Diagonally non-computable sequences and randomness

Recall that a sequence X is diagonally non-computable if there is some total function $f \leq_T X$ such that $f(e) \neq \phi_e(e)$ for every e.

Every Martin-Löf random sequence X is diagonally non-computable:

Let $f(e) = X \upharpoonright e$ (coded as a natural number).

Note that $f(e) < 2^{e+1}$.

DNC_h functions

Let h be a computable, non-decreasing, unbounded function.

- f is a DNC_h function if
 - f is total,
 - $f(e) \neq \phi_e(e)$ for every e, and
 - f(e) < h(e) for every e.

Theorem (Bienvenu, Porter) DNC_h is a deep class if and only if $\sum_{n=0}^{\infty} \frac{1}{h(n)} = \infty$.

Moreover, if $\sum_{n=0}^{\infty} \frac{1}{h(n)} < \infty$, then every Martin-Löf random computes a DNC_h function.

Thank you for your attention!
